

Building the AI assistant project on n8n, I initially wasn't aware of how data moves between nodes, as it was my first time using the platform. I learned that each node produces an output, usually in JSON format, which can then be used by the nodes that follow it. What I found interesting was that when I needed information from an earlier node later in the workflow, I could reference that node's data directly instead of creating additional connections back to it. This helped keep the workflow visually clean while still allowing later steps to use information generated earlier. Working with this also made concepts such as JSON, schemas and referencing data much clearer to me. I can now better understand how structured data moves between different parts of a system, which is also useful when working with technologies such as Kotlin for mobile application development.
